1. Referencia

Algorítmo	Parámetros	Función
sort, stable_sort	f, 1	ordena el intervalo
nth_element	f, nth, l	void ordena el n-esimo, y
		particiona el resto
fill, fill_n	f, l / n, elem	void llena [f, l) o [f,
		f+n) con elem
lower_bound, upper_bound	f, l, elem	it al primer / ultimo donde se
		puede insertar elem para que
		quede ordenada
binary_search	f, l, elem	bool esta elem en [f, l)
copy	f, l, resul	hace $resul+i=f+i \ \forall i$
find, find_if, find_first_of	f, l, elem	it encuentra i \in [f,l) tq. i=elem,
	/ pred / f2, l2	$pred(i), i \in [f2, l2)$
count, count_if	f, l, elem/pred	cuenta elem, pred(i)
search	f, l, f2, l2	busca $[f2,l2) \in [f,l)$
replace, replace_if	f, l, old	cambia old / pred(i) por new
	/ pred, new	
reverse	f, 1	da vuelta
partition, stable_partition	f, l, pred	pred(i) ad, !pred(i) atras
min_element, max_element	f, l, [comp]	$it \min, \max de [f,l]$
lexicographical_compare	f1,l1,f2,l2	bool con [f1,l1];[f2,l2]
$next/prev_permutation$	f,l	deja en [f,l) la perm sig, ant
set_intersection,	f1, l1, f2, l2, res	[res,) la op. de conj
set_difference, set_union,		
$set_symmetric_difference,$		
push_heap, pop_heap,	f, l, e / e /	mete/saca e en heap [f,l),
make_heap		hace un heap de [f,l)
is_heap	f,l	bool es [f,l) un heap
accumulate	f,l,i,[op]	$T = \sum_{l} / \text{oper de [f,l)}$
inner_product	f1, l1, f2, i	$T = i + [f1, 11) \cdot [f2, \dots)$
partial_sum	f, l, r, [op]	$r+i = \sum /oper de [f,f+i] \forall i \in [f,l)$
builtin_ffs	unsigned int	Pos. del primer 1 desde la derecha
_builtin_clz	unsigned int	Cant. de ceros desde la izquierda.
_builtin_ctz	unsigned int	Cant. de ceros desde la derecha.
_builtin_popcount	unsigned int	Cant. de 1's en x.
_builtin_parity	unsigned int	1 si x es par, 0 si es impar.
_builtin_XXXXXXII	unsigned ll	= pero para long long's.

2. Estructuras

2.1. RMQ (static)

```
1 // Dado un arreglo y una operacion asociativa idempotente:
2 // get(i, j) opera sobre el rango [i, j).
3 // Restriccion: 2^K > N. Usar [] para llenar
  // el arreglo y luego build().
   struct RMQ {
       const static int K = ;
       tipo vec[K][1 << K];
       tipo &operator [](int p){ return vec[0][p]; }
       tipo get(int i, int j){ // intervalo [i, j)
           int p = 31 - \_builtin\_clz(j - i);
10
           return min(vec[p][i], vec[p][j - (1 << p)]);</pre>
11
       }
12
       void build(int n){ // O(n log n)
13
           int mp = 31 - __builtin_clz(n);
14
           forn(p, mp)
15
               forn(x, n - (1 << p))
16
                   vec[p + 1][x] = min(vec[p][x], vec[p][x + (1 << p)]);
17
18
19 };
```

2.2. RMQ (dynamic)

```
1 // Dado un arreglo y una operacion asociativa con neutro:
2 // get(i, j) opera sobre el rango [i, j).
   typedef int node; // Tipo de los nodos
   #define MAXN 100000
   #define operacion(x, y) max(x, y)
   const int neutro = 0;

14
       while(p->cost >= x.cost){
15
         if(p==s.begin()){s.erase(p); break;}
16
         s.erase(p--);
17
18
    }
19
     s.insert(x);
20
21
   int get(int gain){//minimo costo de obtener tal ganancia
     set<V>::iterator p=s.lower_bound((V){gain, 0});
23
     return p==s.end()? INF : p->cost;}
24
2.18. Set con indices
  #include <cassert>
2
   #include <ext/pb_ds/assoc_container.hpp>
   #include <ext/pb_ds/tree_policy.hpp>
   using namespace __gnu_pbds;
   typedef tree<int,null_type,less<int>,//key,mapped type, comparator
       rb_tree_tag,tree_order_statistics_node_update> Set;
   //find_by_order(i) devuelve iterador al i-esimo elemento
  //order_of_key(k): devuelve la pos del lower bound de k
  //Ej: 12, 100, 505, 1000, 10000.
```

//order_of_key(10) == 0, order_of_key(100) == 1,

//order_of_key(707) == 3, order_of_key(9999999) == 5

3. Algoritmos

3.1. Longest Increasing Subsecuence

```
const int MAXN = 1e5+10, INF = 1e8;
2
    //Para non-increasing, cambiar comparaciones y revisar busq binaria
   //Given an array, paint it in the least number of colors so that each
       color turns to a non-increasing subsequence.
  //Solution:Min number of colors=Length of the longest increasing
       subsequence
  int N, a[MAXN];//secuencia y su longitud
   pii d[MAXN+1];//d[i]=ultimo valor de la subsecuencia de tamanio i
   int p[MAXN];//padres
   vector<int> R;//respuesta
   void rec(int i){
     if(i==-1) return;
11
     R.pb(a[i]);
12
     rec(p[i]);
13
14
   int lis(){//O(nlogn)
15
     d[0] = pii(-INF, -1); forn(i, N) d[i+1]=pii(INF, -1);
16
     forn(i, N){
17
       int j = upper_bound(d, d+N+1, pii(a[i], INF))-d;
18
       if (d[j-1].first < a[i] \&\&a[i] < d[j].first) { // check < por <= en d[}
19
           i-1]
         p[i]=d[j-1].second;
20
         d[j] = pii(a[i], i);
^{21}
^{22}
23
     R.clear();
^{24}
     dforsn(i, 0, N+1) if(d[i].first!=INF){
25
       rec(d[i].second);//reconstruir
26
       reverse(R.begin(), R.end());
27
       return i;//longitud
^{28}
     }
29
     return 0;
30
  |}
31
```

3.2. Alpha-Beta prunning

```
1 | 11 alphabeta(State &s, bool player = true, int depth = 1e9, 11 alpha = -
INF, 11 beta = INF) { //player = true -> Maximiza
```

```
if(s.isFinal()) return s.score;
2
     //~ if (!depth) return s.heuristic();
3
       vector<State> children;
4
       s.expand(player, children);
5
       int n = children.size();
6
       forn(i, n) {
           11 v = alphabeta(children[i], !player, depth-1, alpha, beta);
8
           if(!player) alpha = max(alpha, v);
           else beta = min(beta, v);
10
           if(beta <= alpha) break;</pre>
11
12
       return !player ? alpha : beta;}
13
```

3.3. Mo's algorithm

```
int n,sq;
struct Qu{//queries [1, r]
       //intervalos cerrado abiertos !!! importante!!
       int 1, r, id;
   }qs[MAXN];
   int ans[MAXN], curans;//ans[i] = ans to ith query
   bool bymos(const Qu &a, const Qu &b){
       if(a.l/sq!=b.l/sq) return a.l<b.1;
8
       return (a.l/sq)&1? a.r<b.r : a.r>b.r;
9
10
   void mos(){//(n+q)*sqrt(n))*(O(add())+O(remove()))}
11
       forn(i, t) qs[i].id=i;
12
       sort(qs, qs+t, bymos);
13
       int cl=0, cr=0;
14
       sq=sqrt(n);
15
       curans=0;
16
       forn(i, t){ //intervalos cerrado abiertos !!! importante!!
17
            Qu &q=qs[i];
18
           while(cl>q.1) add(--cl);
19
           while(cr<q.r) add(cr++);</pre>
20
           while(cl<q.1) remove(cl++);</pre>
21
           while(cr>q.r) remove(--cr);
22
           ans[q.id]=curans;
23
       }
24
25 }
```

4. Strings

4.1. Manacher

Definición: permite calcular todas las substrings de una string s que son palíndromos de longitud impar (y par, ver observación). Para ello, mantiene un arreglo len tal que len[i] almacena la longitud del palíndromo impar maximal con centro en i.

Explicación algoritmo: muy similar al algoritmo para calcular la función Z. Mantiene el palíndromo que termina más a la derecha entre todos los palíndromos ya detectados. Para calcular len[i], utiliza la información ya calculada si i está dentro de [l, r], y luego corre el algoritmo trivial.

Observación: para calcular los palíndromos de longitud par, basta con utilizar el mismo algoritmo con la cadena $s_0 \# s_1 \# ... \# s_{n-1}$.

```
vi pal_array(string s)
  {
2
       int n = si(s);
3
       s = "@" + s + "$":
       vi len(n + 1);
       int 1 = 1, r = 1;
7
8
       forsn(i, 1, n+1) {
9
           len[i] = min(r - i, len[l + (r - i)]);
10
11
           while (s[i - len[i]] == s[i + len[i]]) len[i]++;
12
13
           if (i + len[i] > r) l = i - len[i], r = i + len[i];
14
       }
15
16
       len.erase(begin(len));
17
       return len;
18
19 }
```

4.2. KMP

```
// pref[i] = max borde de s[0..i] = failure function al intentar
    matchear con s[i+1]
vi prefix_function(string &s) {
    int n = si(s); vi pi(n);
    forsn(i, 1, n) {
        int j = pi[i-1];
        while (j > 0 && s[i] != s[j]) j = pi[j-1];
```

```
if (s[i] == s[j]) j++;
           pi[i] = j;
8
       }
9
       return pi;
10
   }
11
12
   vi find_occurrences(string &s, string &t) {

36 }tri;
```

4.8. Suffix Automaton

Definición Un suffix automaton A es un autómata minimal que reconoce los sufijos de una cadena s.

Conceptos importantes

- lacktriangleq A reconoce a una cadena s si comenzando desde el nodo inicial llegamos a un terminal.
- \blacksquare Llamamos endpoints de una cadena u en sa las posiciones i tal que $u=s_{i-|u|,i-1}$
- Dos substrings u y v de s son equivalentes si recorrer el autómata con u y con v nos lleva al mismo nodo. Esto equivale a que los endpoints de u y de v en s sean los mismos.

- Los nodos del automáta corresponden a las *clases de equivalencia* bajo la relación anterior.
- Si tomamos la *cadena minimal* de una clase y removemos la primera letra, nos movemos al padre en el *suffix tree* de s'. Esto se señaliza mediante *suffix links*.
- Si tomamos la *cadena maximal* de una clase y agregamos una letra al principio, nos movemos a otra clase de equivalencia, recorriendo un *suffix link* en sentido inverso, es decir, nos movemos a los hijos en el suffix tree de s'.

Problemas clásicos

- lacktriangle Determinar si w es subcadena de s: simplemente correr el autómata.
- Determinar si w es sufijo de s: correr el autómata y ver si caemos en un terminal.
- Contar cantidad de subcadenas distintas de s: esto es igual a la cantidad de caminos en el autómata y se calcula mediante una DP.
- Contar cantidad de apariciones de w en s: correr autómata con w. Llamemos u al nodo en el que terminamos, la cantidad de apariciones es la cantidad de caminos en A que comienzan en u y llegan a un terminal.
- Encontrar dónde aparece w por primera vez en s: correr autómata con w. Llamemos u al nodo en el que terminamos, esto equivale a calcular el camino más largo del autómata a partir del nodo u.
- Encontrar las posiciones de todas las apariciones de w en s: agregar '\$á s, encontrar el nodo u en el que finaliza w, armar el suffix tree, encontrar todas las hojas en el subárbol con raíz en u, cada hoja corresponde a un prefijo y por lo tanto a una aparición.

```
struct state {
     int len, link;
2
     map<char,int> next;
3
     state() { }
4
5
   const int MAXLEN = 1e5+10;
   state st[MAXLEN*2];
   int sz, last;
   void sa_init() {

```

4.9. Z Function

Definición La función Z para una string s de longitud n es un arreglo a de la misma longitud tal que a[i] es la $m\'{a}xima$ cantidad de caracteres comenzando desde la posición i que coinciden con los primeros caracteres de s. Es decir, es el $m\'{a}ximo$ prefijo $com\'{u}n$. **Observación** z[0] no está bien definido, pero se asume igual a 0.

Algoritmo La idea es mantener el máximo match (es decir, el segmento [l, r] con máximo r tal que se sabe que s[0..r-l]=s[l..r]).

Siendo i el índice actual (del que queremos calcular la función Z), el algoritmo se divide en dos casos:

- \bullet i > r: la posición está fuera de lo que hemos procesado. Se corre el algoritmo trivial.
- i <= r: la posición está dentro del *match actual*, por lo que se puede utilizar como aproximación inicial z[i] = min(r-i+1, z[i-l]), y luego correr el algoritmo trivial.

Problemas clásicos

■ Buscar una subcadena: concatenamos p con t (utilizando un separador). Hay una aparición si la función Z matcheó tantos caracteres como la longitud de p.

```
| int z[N]; // z[i] = i==0 ? 0 : max k tq s[0,k) match with s[i,i+k)
   void z_function(string &s, int z[]) {
       int n = si(s);
3
       forn(i,n) z[i]=0:
4
      for (int i = 1, l = 0, r = 0; i < n; ++i) {
5
          if (i <= r) z[i] = min (r - i + 1, z[i - 1]);
6
          while (i + z[i] < n \&\& s[z[i]] == s[i + z[i]]) ++z[i];
          if (i + z[i] - 1 > r) l = i, r = i + z[i] - 1;
8
       }
9
10
```

4.10. Palindrome

```
bool palindrome(11 x){
string s = to_string(x); int n = si(s);
forn(i,n/2) if(s[i] != s[n-i-1]) return 0;
return 1;
}
```

5. Geometría

5.1. Punto

```
1 struct pto{
     double x, y;
     pto(double x=0, double y=0):x(x),y(y){}

```

6. DP Opt

Observaciones:

A[i][j] el menor k que logra la solución óptima. En Knuth y D&C la idea es aprovechar los rangos determinados por este arreglo.

6.1. Knuth

Problema de ejemplo: dado un palito de longitud l, con n puntos en los que se puede cortar, determinar el costo mínimo para partir el palito en n+1 palitos unitarios (la DP se puede adaptar a k agregando un parámetro extra), donde hay un costo fijo por partir el rango i,j que cumple la condición suficiente. Una función de costos que cumple es la distancia entre los extremos j-i. El problema clásico de esta pinta es el del ABB óptimo.

```
Recurrencia original: dp[i][j] = min_{i < k < j} dp[i][k] + dp[k][j] + C[i][j]
Condición suficiente: A[i, j-1] \le A[i, j] \le A[i+1, j]
```

Es decir, si saco un elemento a derecha el óptimo se mueve a izquierda o se mantiene, y análogo si saco un elemento a izquierda.

Complejidad original: $O(n^3)$

Complejidad optimizada: $O(n^2)$

Solución: iteramos por el tamaño len del subarreglo (creciente), y para cada extremo izquierdo l, determinamos el extremo derecho r = l + len e iteramos por los k entre A[l][r-1] y A[l+1][r], actualizando la solución del estado actual.

6.2. Chull

Problema de ejemplo:

Recurrencia original:

Condición suficiente:

Complejidad original:

Complejidad optimizada:

Solución:

6.3. Divide & Conquer

Problema de ejemplo: dado un arreglo de n números con valores a_1, a_1, \ldots, a_n , dividirlo en k subarreglos, tal que la suma de los cuadrados del peso total de cada subarreglo es mínimo.

Recurrencia original: $dp[i][j] = min_{k < j} dp[i-1][k] + C[k][j]$

Condición suficiente: $A[i][j] \leq A[i][j+1]$ o (normalmente más fácil de probar) $C[a][d] + C[b][c] \geq C[a][c] + C[b][d]$, con a < b < c < d..

La segunda condición suficiente es la intuición de que no conviene que los intervalos se crucen.

Complejidad original: $O(kn^2)$

Complejidad optimizada: $O(kn\log(n))$

Solución: la idea es, para un i determinado, partir el rango $[j_{left}, j_{right})$ al que pertenecen los j que queremos calcular a la mitad, determinar el óptimo y utilizarlo como límite para calcular los demás. Para implementar esto de forma sencilla, se suele utilizar la función recursiva $dp(i, j_{left}, j_{right}, opt_{left}, opt_{right})$ que se encarga de, una vez fijado el punto medio m del rango $[j_{left}, j_{right})$ iterar por los k en $[j_{left}, j_{right})$ para determinar el óptimo opt para m, y continuar calculando $dp(i, j_{left}, m, opt_{left}, opt)$ y $dp(i, m, j_{right}, opt, opt_{right})$.

7. Matemática

7.1. Teoría de números

7.1.1. Teorema de Wilson

 $(p-1)! \equiv -1 \pmod{p}$ Siendo p primo.

7.1.2. Pequeño teorema de Fermat

 $a^p \equiv a \pmod{p}$ Siendo p primo.

7.1.3. Teorema de Euler

$$a^{\varphi(n)} \equiv 1 \pmod{n}$$

7.2. Numeros combinatorios copados y como calcularlos

7.2.1. Combinatorios

7.2.2. Lucas Theorem

7.2.3. Stirling

7 }

 $\binom{n}{k}$ = cantidad de formas de particionar un conjunto de n elementos en m subconjuntos no vacíos.

7.2.4. Bell

 $B_n = \text{cantidad}$ de formas de particionar un conjunto de n elementos en subconjuntos no vacíos.

$$B_{0} = B_{1} = 1$$

$$B_{n+1} = \sum_{k=0}^{n} \binom{n}{k} B_{k}.$$

$$B_{n} = \sum_{k=0}^{n} \binom{n}{k}.$$

int bell[MAXC+1] [MAXC+1];

ll bell(int n){
bell[0] = 1;
forsn(i,1,n+1) forsn(k,0,i)
bell[i] = add(bell[i],mul(C[i-1][k],bell[k]));

}

7.2.5. Eulerian

 $A_{n,m}$ = cantidad de permutaciones de 1 a n con m ascensos (m elementos mayores que el anterior).

$$A(n,m) = (n-m)A(n-1,m-1) + (m+1)A(n-1,m).$$

7.2.6. Catalan

 C_n = cantidad de árboles binarios de n+1 hojas, en los que cada nodo tiene cero o dos hijos.

$$C_n = {2n \choose n} - {2n \choose n-1} \quad \text{con } n \ge 1.$$

$$C_0 = 1 \quad \text{y} \quad C_{n+1} = \sum_{i=0}^n C_i C_{n-i} \quad \text{con } n \ge 0.$$

7.3. Heron's formula

It states that the area of a triangle whose sides have lengths a, b, and c is $A = \sqrt{s(s-a)(s-b)(s-c)}$, where s is the semiperimeter of the triangle; that is, $s = \frac{a+b+c}{2}$.

7.4. Sumatorias conocidas

$$\sum_{i=0}^{n} {n \choose i} = 2^n$$
$$\sum_{i=0}^{n} i {n \choose i} = n * 2^{n-1}$$

$$\begin{split} \sum_{i=m}^{n} i &= \frac{n(n+1)}{2} - \frac{m(m-1)}{2} = \frac{(n+1-m)(n+m)}{2} \\ \sum_{i=0}^{n} i &= \sum_{i=1}^{n} i = \frac{n(n+1)}{2} \\ \sum_{i=0}^{n} i^{2} &= \frac{n(n+1)(2n+1)}{6} = \frac{n^{3}}{3} + \frac{n^{2}}{2} + \frac{n}{6} \\ \sum_{i=0}^{n} i(i-1) &= \frac{8}{6} \left(\frac{n}{2}\right) \left(\frac{n}{2} + 1\right) (n+1) \text{ (doubles)} \to \text{Sino ver caso impar y par} \\ \sum_{i=0}^{n} i^{3} &= \left(\frac{n(n+1)}{2}\right)^{2} = \frac{n^{4}}{4} + \frac{n^{3}}{2} + \frac{n^{2}}{4} = \left[\sum_{i=1}^{n} i\right]^{2} \\ \sum_{i=0}^{n} i^{4} &= \frac{n(n+1)(2n+1)(3n^{2}+3n-1)}{30} = \frac{n^{5}}{5} + \frac{n^{4}}{2} + \frac{n^{3}}{3} - \frac{n}{30} \\ \sum_{i=0}^{n} i^{p} &= \frac{(n+1)^{p+1}}{p+1} + \sum_{k=1}^{p} \frac{B_{k}}{p-k+1} {p \choose k} (n+1)^{p-k+1} \end{split}$$

7.5. Ec. Característica

```
a_0T(n) + a_1T(n-1) + \dots + a_kT(n-k) = 0
p(x) = a_0x^k + a_1x^{k-1} + \dots + a_k
Sean r_1, r_2, \dots, r_q las raíces distintas, de mult. m_1, m_2, \dots, m_q
T(n) = \sum_{i=1}^q \sum_{j=0}^{m_i-1} c_{ij} n^j r_i^n
Las constantes c_{ij} se determinan por los casos base.

7.25. FFT y NTT

Base teórica

Dado el espacio lineal con producto interno (definido como una integral loca) E, de funciones continuas definidas por partes $f: [-\pi, \pi] \to \mathbb{C}$, un **sistema ortonormal cerrado infinito** es $\{1/\sqrt(2), \sin(x), \cos(x), \sin(2x), \cos(2x), \ldots\}$. Por lo tanto, cualquier funcion $f \in E$ puede ser representada por $\sum_{n=1}^{\infty} \langle f, e_n \rangle e_n$. Esta combinación lineal (utilizando la sumatoria y el sistema ya definidos), es la **serie de Fourier**.

También se puede definir la serie compleja de Fourier mediante el sistema $\{1, e^{ix}, e^{-ix}, e^{i2x}, e^{-i2x}, \ldots\}$.

Una **transformada de Fourier** permite trabajar con funciones que no están restringidas al intervalo $[-\pi,\pi]$. La principal diferencia es que el sistema ortonormal pasa de ser discreto a continuo.

Sin embargo, existe una versión discreta de la transformada, la **transformada discreta de Fourier** (DFT).

Una de las propiedades importantes de la transformada es que la **convolución** de funciones sin transformar se traduce en multiplicar las transformadas.

FFT, el algoritmo para calcular rápidamente la DFT, se basa en que dado un polinomio A(x), $A(x) = A_0(x^2) + x * A_1(x^2)$, donde $A_0(x)$ y $A_1(x)$ son los polinomios que se forman al tomar los términos pares e impares respectivamente.

 \mathbf{NTT} es un algoritmo más lento pero más preciso para calcular la DFT, ya que trabaja con enteros módulo un primo p.

```

8. Grafos

8.1. Teoremas y fórmulas

8.1.1. Teorema de Pick

$$A = I + \frac{B}{2} - 1$$

Donde A es el área, I es la cantidad de puntos interiores, y B la cantidad de puntos en el borde.

8.1.2. Formula de Euler

$$v - e + f = k + 1$$

Donde v es la cantidad de vértices, e la cantidad de arcos, f la cantidad de caras y kla cantidad de componentes conexas.

8.2. Dijkstra

```
vector<pii> adj[N]; // IMPORTANTE: ver tipo arco
2 //To add an edge (u,v) with cost p use G[u].pb(v,p)

     input stream into str. If we use cin >> str it would read until it
    finds a whitespace
// Make an extra call if we previously read another thing from the input
      stream (otherwise it wouldn't work as expected)
cout << fixed << setprecision(n); // Sets the decimal precision to be
     used to format floating-point values on output operations to n
cout << setw(n); // Sets the field width to be used on output operations</pre>
 cout << setfill('0'); // Sets c as the stream's fill character</pre>
 Increment stack size to the maximum (Linux):
 // #include <sys/resource.h>
struct rlimit rl;
getrlimit(RLIMIT_STACK, &rl);
rl.rlim_cur = rl.rlim_max;
setrlimit(RLIMIT_STACK, &rl);
String to int and vice versa (might be very useful to parse odd things):
 template <typename T> string to_str(T str) { stringstream s; s << str;
    return s.str(); }
 template <typename T> int to_int(T n) { int r; stringstream s; s << n; s
      >> r; return r; }
C++11:
to_string(num) // returns a string with the representation of num
```

14. Ayudamemoria

Cant. decimales

```
#include <iomanip>
cout << setprecision(2) << fixed;</pre>
```

Rellenar con espacios(para justificar)

```
#include <iomanip>
cout << setfill(''') << setw(3) << 2 << endl;</pre>
```

Comparación de Doubles

```
const double EPS = 1e-9;
    x == y <=> fabs(x-y) < EPS
    x > y <=> x > y + EPS
    x >= y <=> x > y - EPS
```

Limites

Muahaha

```
#include <signal.h>
void divzero(int p){
while(true);}
void segm(int p){
exit(0);}
//in main
```

```
signal(SIGFPE, divzero);
8 signal(SIGSEGV, segm);
Mejorar velocidad 2
1 //Solo para enteros positivos
  inline void Scanf(int& a){
    char c = 0;
    while(c<33) c = getc(stdin);</pre>
    a = 0;
    while(c>33) a = a*10 + c - '0', c = getc(stdin);
7 }
Leer del teclado
freopen("/dev/tty", "a", stdin);
Iterar subconjunto
for(int sbm=bm; sbm; sbm=(sbm-1)&bm)
File setup
_{1} |// tambien se pueden usar comas: {a, x, m, 1}
touch {a..l}.in; tee {a..l}.cpp < template.cpp
Releer String
1 string s; int n;
getline(cin, s);
stringstream leer(s);
  while(leer >> n){
    // do something ...
6 }
```
